

# SHOULD WE WORRY ABOUT MILD DISABILITY ?

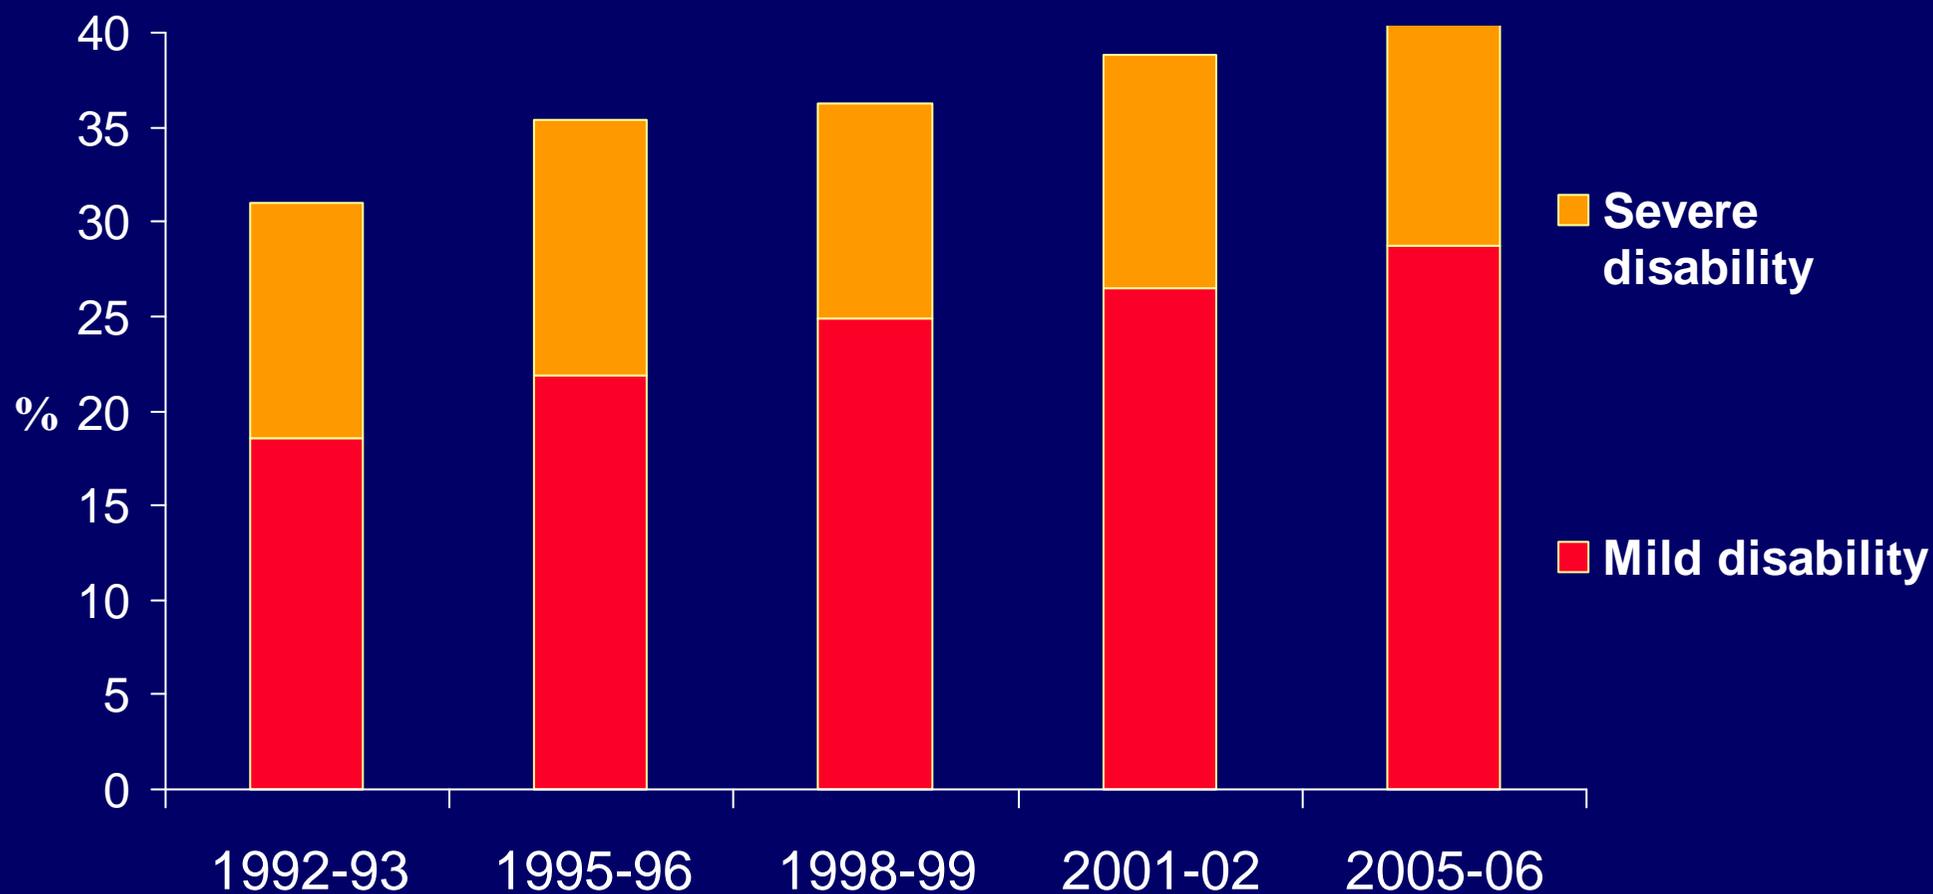

*Dorly Deeg, PhD*

Department of Psychiatry and  
EMGO Institute for Health and Care Research  
VU University Medical Centre, Amsterdam  
The Netherlands

# Background

- Contrasting scenario's: compression vs. expansion of morbidity & disability
- Dynamic equilibrium scenario (Manton 1982): fewer years with severe disability, more years with mild disability
- Latter observed in many countries, including The Netherlands
- Importance of distinction mild vs. severe disability

## Prevalence of mild, not severe disability increases (ages 65-84, The Netherlands)

Longitudinal Aging Study Amsterdam, GALI, age-sex weights ~ population in each year

## Research question

Should an increase in mild disability be a concern to health policy?

Or:

What is the predictive ability of mild disability for unfavourable outcomes over time?

Longitudinal  
Aging  
Study  
Amsterdam

# Longitudinal Aging Study Amsterdam

**Random sample  
across the Netherlands**

**4109 men and women**

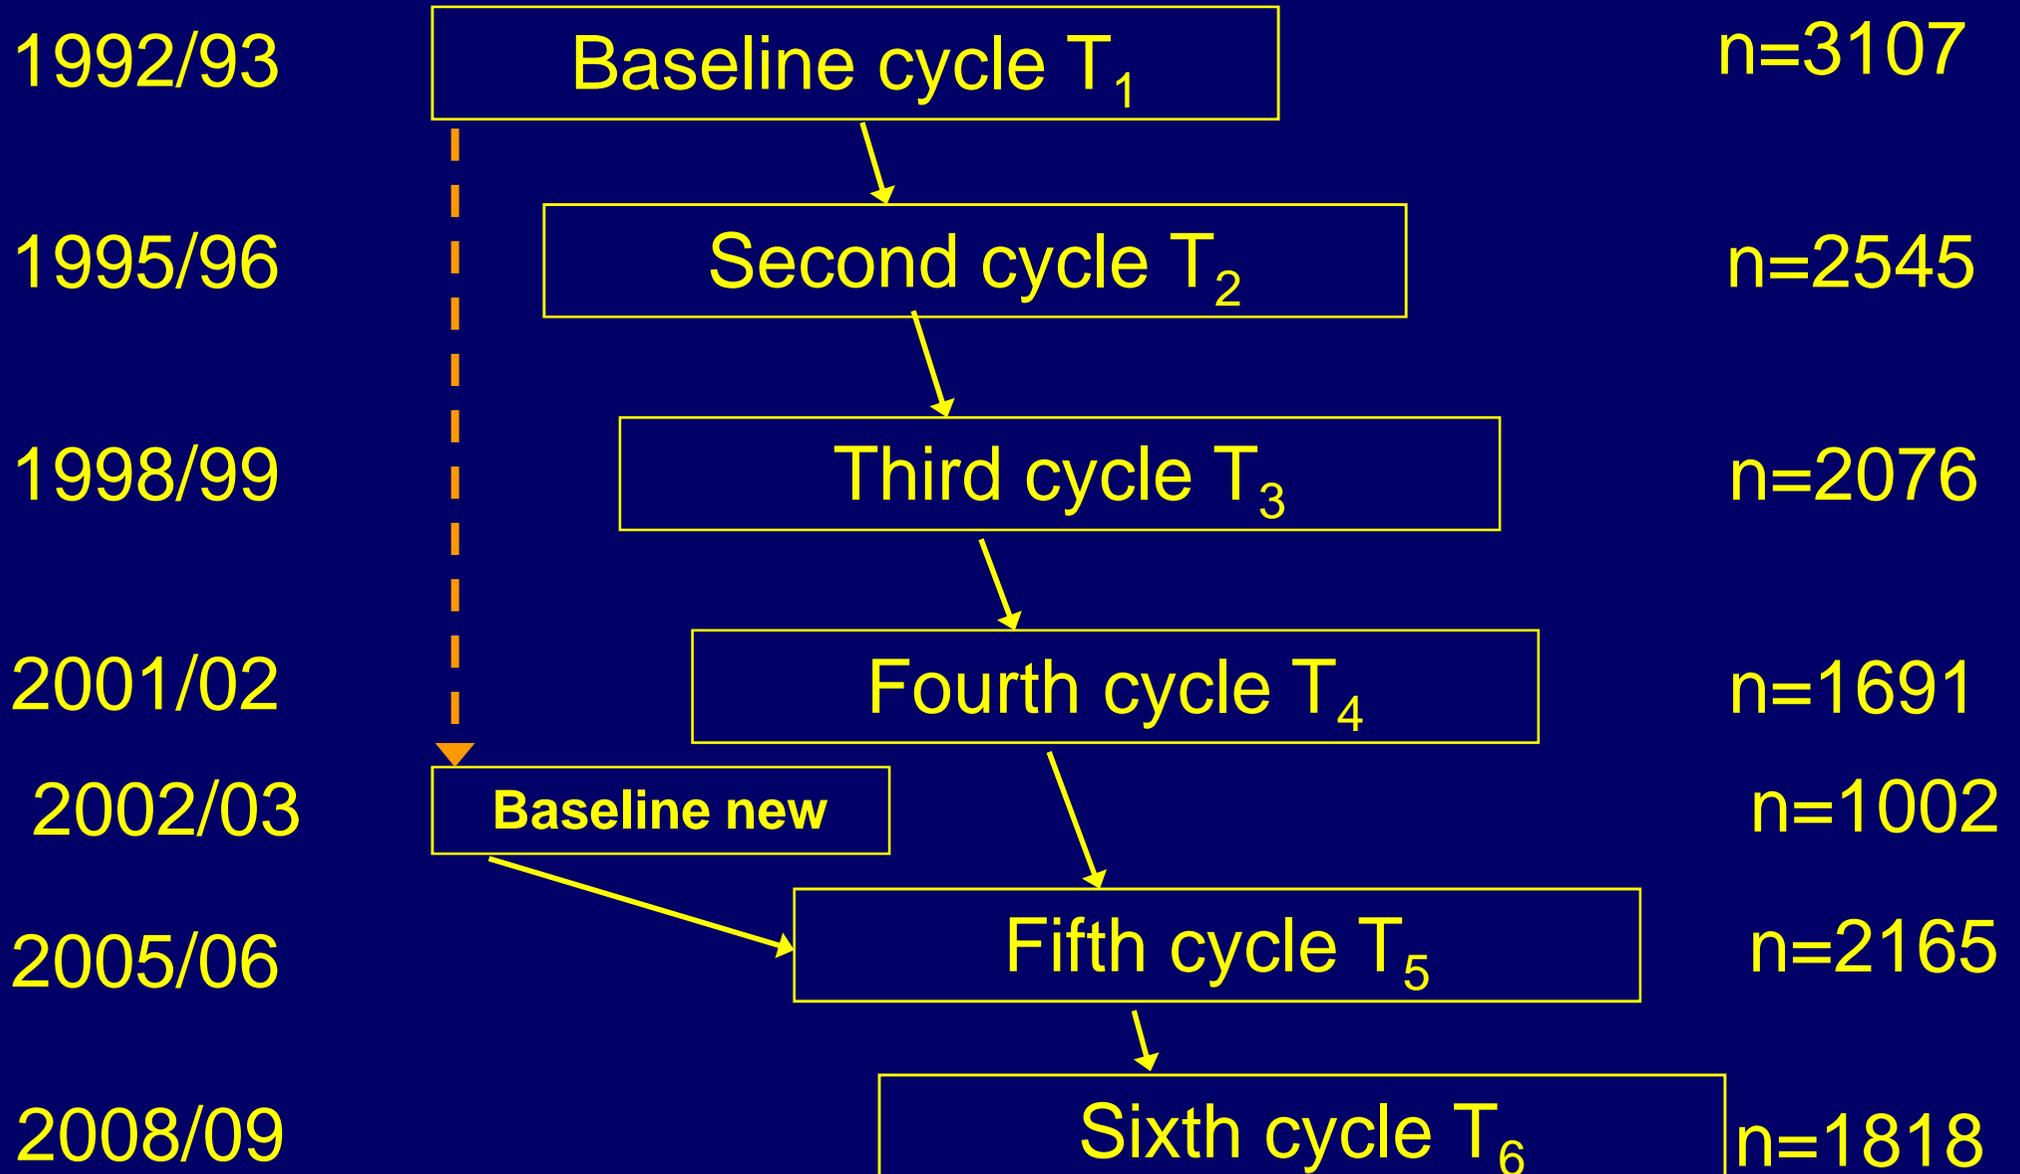

**Initial ages 55-85**

**Start 1992 and 2002**

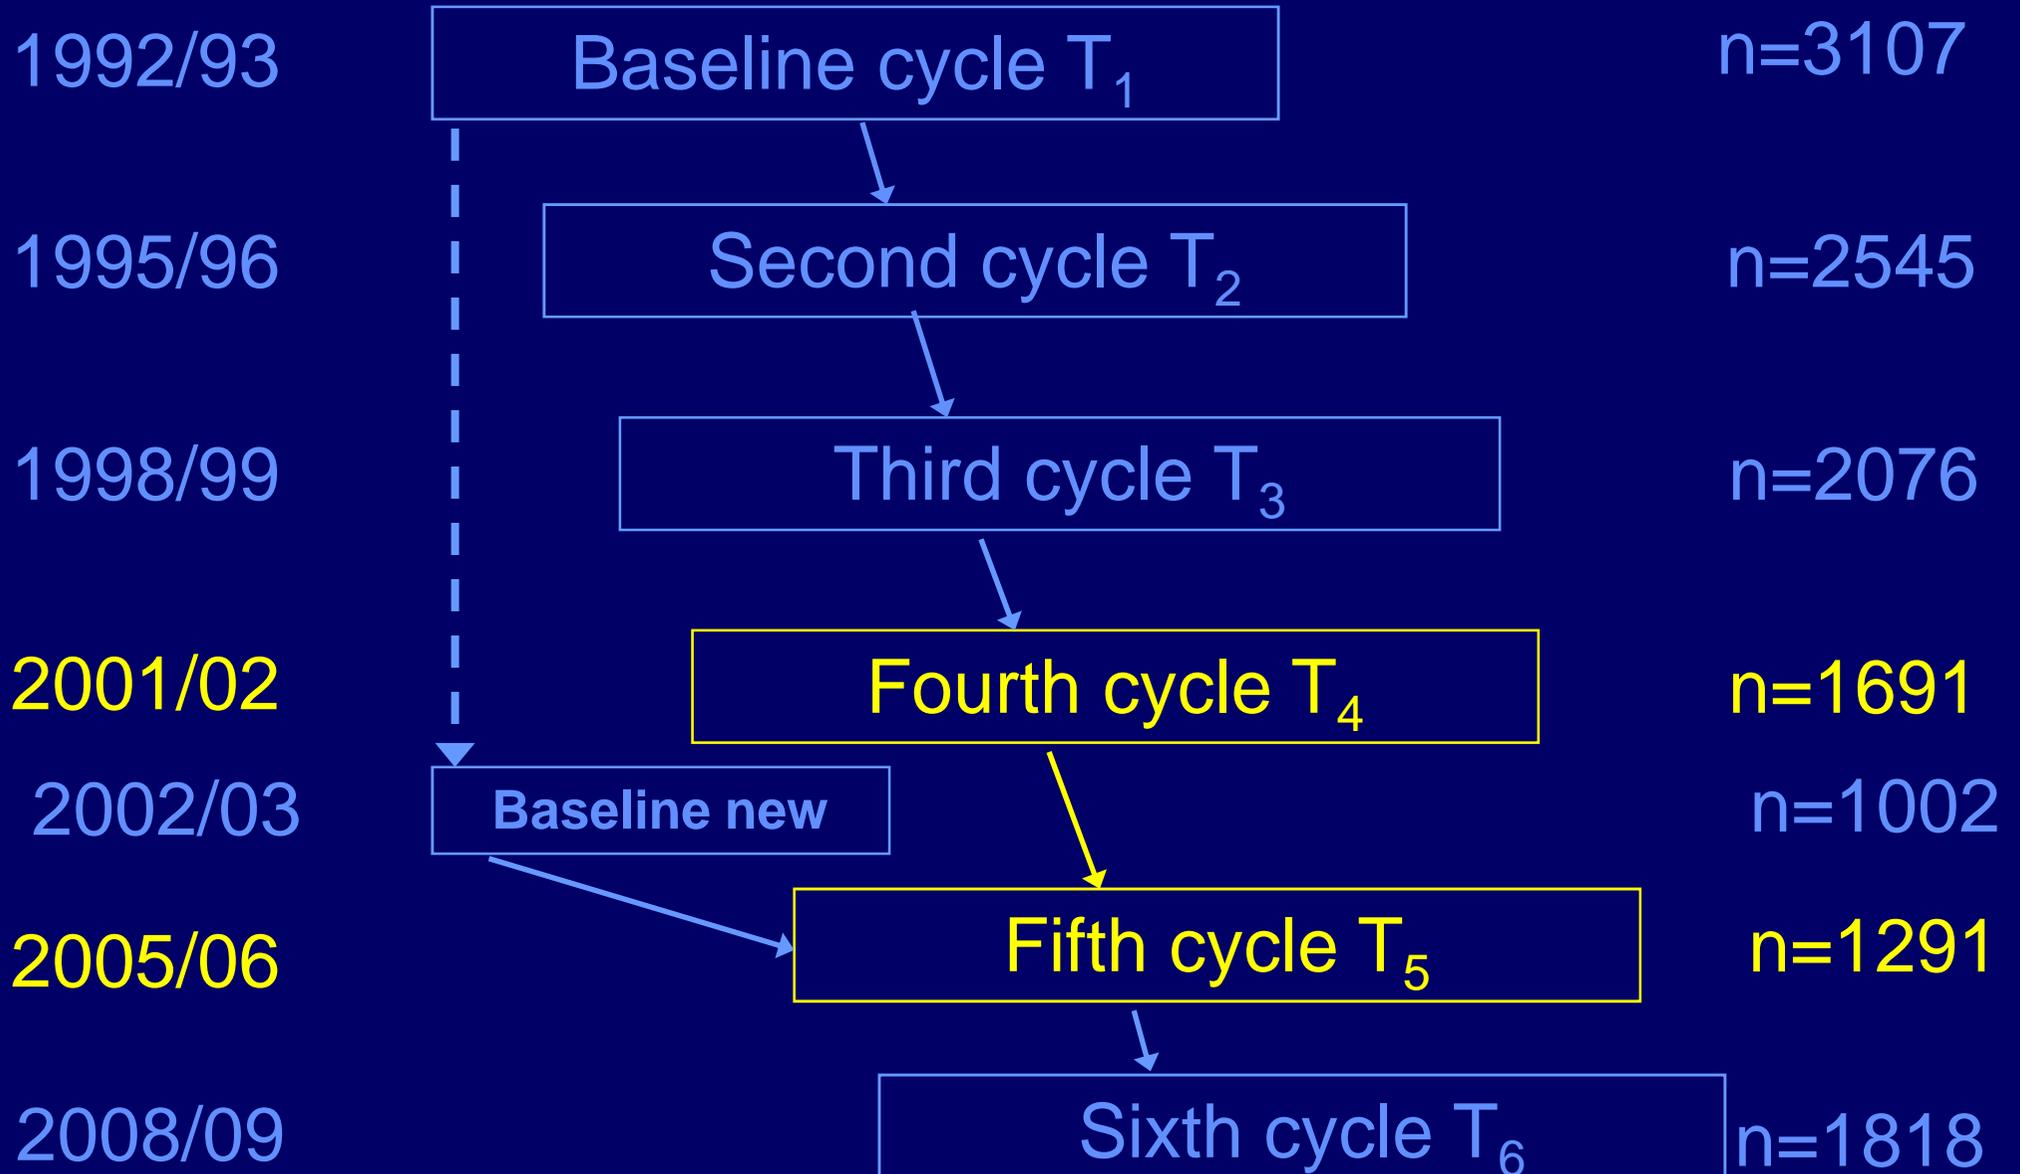

**3-year intervals**

# LASA time schedule

# LASA time schedule

# Design

Initial ages 64-94 years

N (follow-up) = 876 – 998, depending on outcome

*Unfavourable outcomes:*

Follow-up 4 years for

- Severe disability
- Needing help with personal care
- Institutionalisation

Follow-up 5 years of

- Mortality

# Disability measures

*Physical Performance Score, based on quartiles of time needed for:*

- Walk 2x3 meter
- Chair stands 5x
- Putting on and taking off cardigan
- Tandem stand 10 seconds

N = 1335

0 (minimum ability) ... 16 (maximum ability)

**Mild** disability: 1 SD < median (scores 5-9)

**Severe** disability: < 5

*Self-report of Global Activity Limitation > 3 months (GALI):*

no disability / **mild** disability / **severe** disability

N = 1453

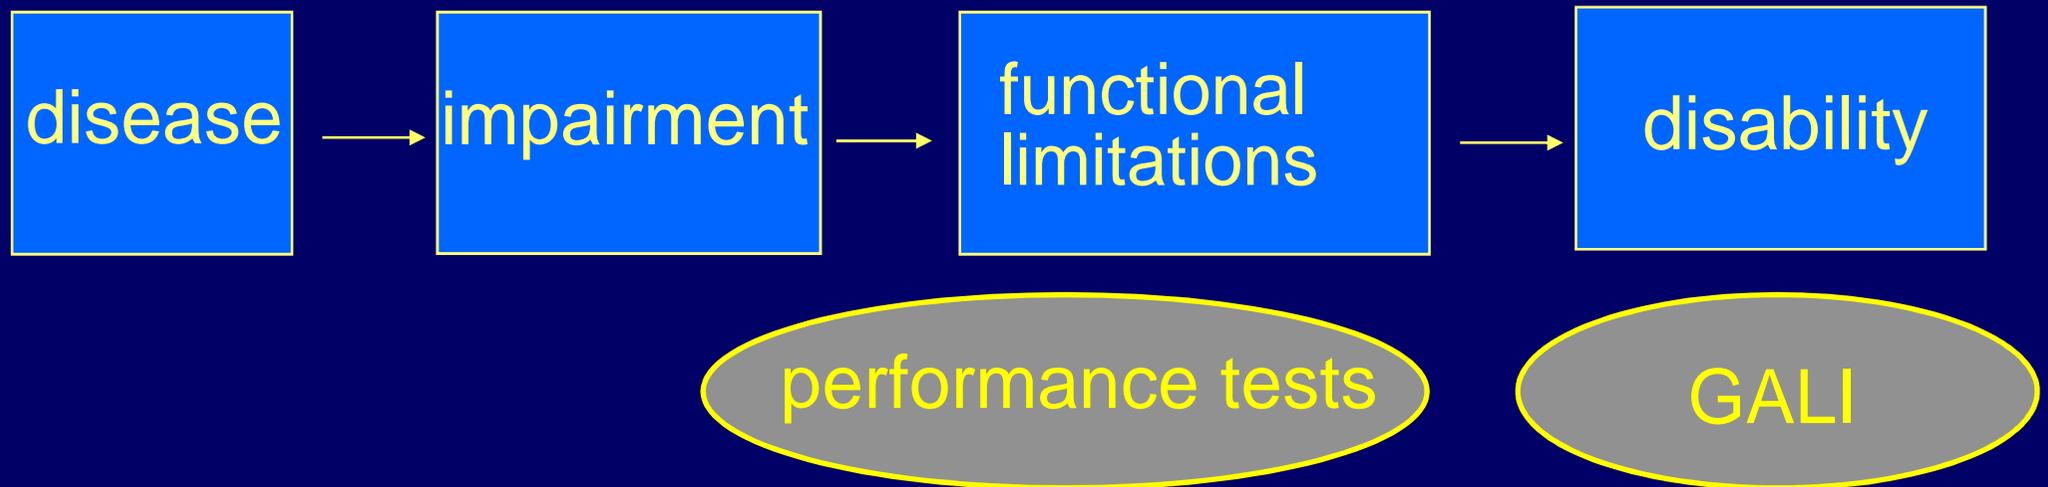

# Overlap performance-based / self-reported disability at baseline

<i>Performance-based</i>	<i>Self-report</i>			<i>Total</i>
	<i>No</i>	<i>Mild</i>	<i>Severe</i>	
<i>No</i>	<b>75%</b>	22%	3%	100%
<i>Mild</i>	53%	<b>34%</b>	13%	100%
<i>Severe</i>	34%	24%	<b>42%</b>	100%

Agreement in scores = 56%

Spearman correlation = 0.37

# The disablement process

# Baseline prevalence and transition rates

	<i>Disability</i>	
	<i>Performance-based</i>	<i>Self-report</i>
Mild	34%	27%
Severe	16%	14%
Mild → severe	30%	20%
Mild → personal care	10%	8%
Mild → institutionalisation	3%	4%
Mild → death	17%	19%

Transitions among those without the 'unfavourable' condition at baseline

# Unfavourable outcomes for mild and severe performance-based disability

	<b>Mild disability</b>	<b>p</b>	<b>Severe disability</b>	<b>p</b>
Survived but no data <sup>1</sup>	1.28	0.23	1.57	0.002
Severe disability <sup>1</sup>	15.99	<0.001	-	
Personal care <sup>1</sup>	5.25	<0.001	4.76	<0.001
Institutionalisation <sup>1</sup>	1.91	0.24	11.39	<0.001
Mortality <sup>2</sup>	1.58	0.005	3.06	<0.001

<sup>1</sup> Multinomial logistic regression, those with 'favourable' condition at baseline only, adjusted for age, sex, reference: no disability

<sup>2</sup> Cox regression, adjusted for age, sex

# Unfavourable outcomes for mild and severe self-reported disability

	<b>Mild disability</b>	<b>p</b>	<b>Severe disability</b>	<b>p</b>
Survived but no data <sup>1</sup>	1.13	0.51	1.18	0.18
Severe disability <sup>1</sup>	10.24	<0.001	-	
Personal care <sup>1</sup>	2.19	0.02	4.48	<0.001
Institutionalisation <sup>1</sup>	2.30	0.07	10.02	<0.001
Mortality <sup>2</sup>	1.30	0.04	2.20	<0.001

<sup>1</sup> Multinomial logistic regression, those with 'favourable' condition only, adjusted for age, sex, reference: no disability

<sup>2</sup> Cox regression, adjusted for age, sex

# Population attributable risk (PAR)

How can we compare the impact of mild versus severe disability at the population level?

$$PAR = 100 \times \frac{p (RR-1)}{p (RR-1)+1}$$

Combines prevalence with impact

## Population attributable risks of outcomes for mild and severe disability (both types)

	Mild disability		Severe disability	
	Perf	Self	Perf	Self
Severe disability	83.7	71.4	-	-
Personal care	59.2	24.3	38.1	32.3
Institutionalisation	23.7	26.0	63.0	55.3
Mortality	16.6	7.5	25.2	14.1

# Conclusions

- Mild disability has increasing prevalence (currently about 30%)
- Mild disability has predictive ability for unfavourable outcomes severe disability, needing help with personal care, and mortality (institutionalisation n.s.)
- Population attributable risk of mild disability is substantial, and not much smaller than of severe disability

# Discussion

- Cut points for performance-based mild disability?
- Low rate of institutionalisation
- Adjustment of models for other covariates?
- Specific groups at higher risk?

# Beware of mild disability !
