REVES-Conference  
Havana, Cuba

May 20, 2010

- There is consistent evidence from developed countries showing differences in health outcomes by socioeconomic status.

- There is consistent evidence from developed countries showing differences in health outcomes by socioeconomic status.
- Higher level of education has been associated with:
  - reduced periods of morbidity (Crimmins & Saito 2001).
  - lower likelihood of functional limitation in late life (Freedman & Martin 1999).
  - lower hazard of death (Elo & Preston 1996).

# Background

- Mexican population experienced an important increase in the level of education after the 1930s (Ham-Chande 2003).
- The opening of the economy to forces of globalization resulted in higher returns to better educated people, penalizing those with less schooling (Frank and Finch 2004).
- Mexico's old-age health dynamics are characterized by chronic conditions (currently dominating the morbidity-mortality patterns) and infectious diseases (residual to an earlier epidemiological regime) (Kohler & Soldo 2004).

# Purpose

- In this paper we study how education and sex associate with healthy life expectancy in the Mexican older adult population using a longitudinal dataset.

- I use two waves of the Mexican Health and Aging Study: 2001-2003.
- The baseline sample included 15,186 people who were nationally representative of the 13 million Mexicans born prior to 1951 with national and urban/rural representation.
- In this paper we analyzed a sample of 13,116 aged 50 or older in 2001.

- I use two waves of the Mexican Health and Aging Study: 2001-2003.
- The baseline sample included 15,186 people who were nationally representative of the 13 million Mexicans born prior to 1951 with national and urban/rural representation.
- In this paper we analyzed a sample of 13,116 aged 50 or older in 2001.
- Applied the IMaCh approach developed by Nicolas Brouard and Agnès Lièvre - INED.

- “Disabled” is defined as having at least one difficulty with ADLs (walking, bathing, eating, getting in and out of bed, toileting).
- “Active” is defined as having no difficulties with ADLs.
- Education is categorized into 3 groups based on years of schooling:
  - “No education”: zero years of schooling.
  - “Some Elementary education”: incomplete elementary school (1 to 5 years of schooling).
  - “Elementary +”: completed elementary school or more.

# Sample Distribution by Level of Education and Sex: MHAS 2001

	Women		Men	
	N	%	N	%
No ed	1,907	27.32	1,372	22.36
Some elem	2,506	35.90	2,128	34.69
Elem+	2,568	36.79	2,635	42.95

# Observed Transitions for Men: MHAS 2001-2003

	Status in 2003						
	Active		Disabled		Death		Total
	N	%	N	%	N	%	N
Active	5,265	85.8	256	4.2	163	2.7	5,684
Disabled	212	3.5	153	2.5	86	1.4	451
Total	5,477	89.3	409	6.7	249	4.1	6,135

# Observed Transitions for Women: MHAS 2001-2003

	Status in 2003						
	Active		Disabled		Death		Total
	N	%	N	%	N	%	N
Active	5,674	81.3	431	6.2	133	1.9	6,238

# Conclusion

- People with low level of education are more likely to become disabled.
- There are no differences in the probability of recovering from disability by level of education.
- People with more education have longer total and active life expectancy, and reduced length of time in the disabled state.

- Try alternative measures of disability, e.g., including IADLs.
- Create measure of severity of disability.
- Disaggregate the results by rural/urban regions.
